# 1 Review of Asymptotic Theory

Usually econometrics is about analyzing data from an economic context and has steps including:

- Formulating an appropriate model
- Computing estimates of unknown parameters in such a model
- Quantifying the uncertainty about those estimates
- Use these measures of uncertainty to draw empirical conclusions

Asymptotic theory is usually related to the third step, "Quantifying the uncertainty".

#### 1.1 Basic Setup

- Data :  $\{z_i\}_{i=1}^n$  with joint distribution  $P_n$
- Model: A set  $\mathcal{P}_n$  of potential candidates for  $P_n$ . Restrictions may be imposed as necessary.
- Independent and identically distributed (i.i.d) data

$$P_n = P \times P \cdots \times P$$

• Random variable (vector) of interest:

$$\hat{\theta}_n = f_n(z_1, \cdots, z_n)$$

e.g) estimator, test statistics ...

We are interested in features of the distribution of  $\hat{\theta}_n$  with a finite sample size n, which is usually impossible or impractical. Instead, we typically use asymptotics to derive approximations to the distribution of  $\hat{\theta}_n$ . The general idea is to think of  $\hat{\theta}_n$  as the nth element of an infinite sequence and to calculate the limit of the sequence (if exists).

#### 1.2 Modes of Convergence

#### 1.2.1 Covergence in Probability

**Definition 1.2.1.** A sequence of random variables  $z_n$  is said to **converge in probability** to a random variable z if for any  $\delta > 0$ ,  $\lim_{n \to \infty} P(|z_n - z| \le \delta) = 1$  or equivalently,  $\lim_{n \to \infty} P(|z_n - z| > \delta) = 0$  and we denote as  $z_n \stackrel{p}{\to} z$  or  $p \lim_{n \to \infty} z_n = z$ .

Theorem 1.2.1. (Khintchine's Weak Law of Large Numbers)

If  $z_1, \dots z_n$  are i.i.d with  $E(z_i) = \mu$ , then  $\bar{z}_n \stackrel{p}{\to} \mu$  where  $|\mu| < +\infty$ .

*Proof.* Assume  $Var(z_i) = \sigma^2 < +\infty$ . For any  $\delta > 0$ ,

$$P(|\bar{z}_n - \mu| > \delta) \le \frac{E(|\bar{z}_n - \mu|^2)}{\delta^2}$$
$$= \frac{\sigma^2}{\delta^2 \cdot n}$$
$$\to 0$$

: Chebyshev's Inequality

as  $n \to \infty$ 

# 1.2.2 Convergence in Distribution

**Definition 1.2.2.** Let  $z_n$  be a sequence of random variables and define  $F_n(x) = P(z_n \le x)$ . Let z a random variable of which distribution function is  $F(x) = P(z \le x)$ .  $z_n$  is said to **converge** in **distribution** to z if  $F_n(x) \to F(x)$  as  $n \to \infty$  at all x where F is continuous. We denote this by  $z_n \stackrel{d}{\to} z$ .

- z is usually called the asymptotic distribution of limit distribution of  $z_n$ .
- $z_n \xrightarrow{d} z$  does not necessarily mean that  $z_n$  and z are close (only the cdfs are close) where as  $z_n \xrightarrow{p} z$  implies  $z_n$  and z are close.
- $z_n \stackrel{p}{\to} z$  implies  $z_n \stackrel{d}{\to} z$
- However,  $z_n \xrightarrow{d} z$  don't imply  $z_n \xrightarrow{p} z$ For example, consider  $Y_n$  and Y that are mutually independent with distributions given by

$$Y_n = \begin{cases} 1 \text{ with probability } \frac{1}{2} + \frac{1}{n+1} \\ 0 \text{ with probability } \frac{1}{2} - \frac{1}{n+1} \end{cases}$$
$$Y = \begin{cases} 1 \text{ with probability } \frac{1}{2} \\ 0 \text{ with probability } \frac{1}{2} \end{cases}$$

• If  $z = c \in \mathbb{R} (\Leftrightarrow P(z = c) = 1)$ , that is the limit distribution z is degenerate, then  $z_n \xrightarrow{p} c \Leftrightarrow z_n \xrightarrow{d} c$ 

# Theorem 1.2.2. (Lindeberg-Levy Central Limit Theorem)

Let  $z_1, \dots, z_n$  be i.i.d with  $E(z_i) = \mu, Var(z_i) = \sigma^2$  where  $|\mu| < +\infty, \sigma^2 < +\infty$ . Then

$$\sqrt{n}(\bar{z}_n - \mu) = \frac{1}{\sqrt{n}} \sum_{i=1}^n (z_i - \mu) \xrightarrow{d} N(0, \sigma^2)$$

That is,

$$\lim_{n \to \infty} P(\frac{1}{\sqrt{n}} \sum_{i=1}^{n} (z_i - \mu) \le a) = \int_{-\infty}^{a} \frac{1}{\sqrt{2\pi}\sigma} exp(-\frac{1}{2\sigma^2}x^2) dx.$$

#### Remark. (WLLN and CLT)

By WLLN,  $\bar{X} - \mu \xrightarrow{p} 0$ . In some sense with WLLN,  $\bar{X} - \mu$  goes to 0 too fast as  $n \to \infty$ . Thus by multiplying  $\sqrt{n}$ , the CLT slows down the speed of convergence to make it converge to some non degenerate distribution, i.e,  $\sqrt{n}(\bar{X} - \mu) \xrightarrow{d} Z \sim N(0, \sigma^2)$ .

Similar things hold for random vectors, a vector of random variables. First, let's define random vectors.

$$\begin{aligned} \mathbf{Definition 1.2.3.} \ \boldsymbol{y} &= \begin{pmatrix} y_1 \\ \vdots \\ y_m \end{pmatrix} \in \mathbb{R}^m \text{ is called a } \mathbf{random \ vector}. \text{ We define } E(\boldsymbol{y}) = \begin{pmatrix} E(y_1) \\ \vdots \\ E(y_m) \end{pmatrix} \in \\ \mathbb{R}^m \text{ and } ||\boldsymbol{y}|| &= \sqrt{\boldsymbol{y}^T \boldsymbol{y}} = (y_1^2 + \cdots y_m^2)^{\frac{1}{2}}. \end{aligned}$$

**Theorem 1.2.3.**  $E||\boldsymbol{y}|| < +\infty \Leftrightarrow E|y_j| < +\infty, \forall j = 1, 2, \dots, m$  where m is a finite natural number.

Proof. ( ⇐⇒ ) 
$$y_1^2 + \dots + y_m^2 \le (|y_1| + \dots + |y_m|)^2 \Rightarrow ||y|| \le |y_1| + \dots + |y_m|$$
. So from  $E|y_i| < +\infty$ ,  $E||y|| < +\infty$ .  
( ⇒⇒ )  $|y_j| \le (|y_1|^2 + \dots + |y_m|^2)^{\frac{1}{2}}$ ,  $\forall j = 1, 2, \dots, m \Rightarrow |y_j| \le ||\mathbf{y}||$ ,  $\forall j = 1, 2, \dots, m$ . So from  $E||\mathbf{y}|| < +\infty$ ,  $E|y_j| < +\infty$ ,  $\forall j = 1, 2, \dots, m$ .

Convergence in probability of a random vector is defined as convergence in probability of all elements in the vector. Hence, multivariate version of WLLN (Theorem 1.2.1) holds.

#### Theorem 1.2.4. (WLLN for Random Vectors)

Let  $\boldsymbol{y}_i$  be i.i.d where  $\boldsymbol{y}_i \in \mathbb{R}^m$  s.t.  $E[|\boldsymbol{y}_i|] < +\infty, \forall i$ . Let  $\bar{\boldsymbol{y}}_n = \frac{1}{n} \sum_{i=1}^n \boldsymbol{y}_i = \begin{pmatrix} y_1 \\ \vdots \\ \bar{y}_m \end{pmatrix}$ , then

$$\bar{\boldsymbol{y}}_n \stackrel{p}{\to} E(\boldsymbol{y}_i) = \begin{pmatrix} E(y_{i1}) \\ \vdots \\ E(y_{im}) \end{pmatrix}$$

*Proof.* By definition,  $\bar{\boldsymbol{y}}_n \stackrel{p}{\to} E(\boldsymbol{y}_i)$  if and only if  $\bar{y}_j \stackrel{p}{\to} \mu_j, \forall j = 1, 2, \cdots, m$ . The latter holds if  $E|y_j| < +\infty, \forall j = 1, 2, \cdots, m$  which is equivalent to  $E|\boldsymbol{y}_i| < +\infty$ .

Though Lindeberg-Levy CLT (Theorem 1.2.2) only provides the case for scalar random variables, it can be extended to multivariate data via Cramer-Wold device.

#### Theorem 1.2.5. (Cramer-Wold)

Let  $\hat{\gamma}_n, \gamma_\infty$  be vector-valued random vectors. Then  $\hat{\gamma}_n \xrightarrow{d} \gamma_\infty$  if and only if  $\lambda' \hat{\gamma}_n \xrightarrow{d} \lambda' \gamma_\infty$  for all fixed vectors  $\lambda$  with  $\lambda' \lambda = 1$ .

# Theorem 1.2.6. (Multivariate Lindeberg-Levy Central Limit Theorem)

If  $y_i \in \mathbb{R}^k$  are independent and identically distributed and  $E||y_i||^2 < +\infty$ , then as  $n \to \infty$ 

$$\sqrt{n}(\bar{\boldsymbol{y}}_n - \mu) \stackrel{d}{\to} N(0, V)$$

where  $\mu = E(\mathbf{y})$  and  $V = E((\mathbf{y} - \mu)(\mathbf{y} - \mu)')$ .

*Proof.* Fix some  $\lambda \in \mathbb{R}^k$  such that  $\lambda' \lambda = 1$ . Define  $u_i = \lambda'(\boldsymbol{y}_i - \mu)$ . Then  $u_i$  are i.i.d with  $E(u_i^2) = \lambda' V \lambda < \infty$ . We have

$$\lambda' \sqrt{n} (\bar{\boldsymbol{y}}_n - \mu) = \frac{1}{\sqrt{n}} \sum_{i=1}^n u_i \stackrel{d}{\to} N(0, \lambda' V \lambda)$$

If some random vector  $z \sim N(0, V)$  then  $\lambda' z \sim N(0, \lambda' V \lambda)$ . Thus, we have

$$\lambda' \sqrt{n} (\bar{\boldsymbol{y}}_n - \mu) \stackrel{d}{\to} \lambda' \boldsymbol{z}$$

Since the choice of  $\lambda$  was arbitrary, by Cramer-Wold device (Theorem 1.2.5), we have

$$\sqrt{n}(\bar{\boldsymbol{y}}_n - \mu) \stackrel{d}{\to} \boldsymbol{z}$$

#### 1.2.3 Sufficient Conditions for Joint Weak Convergence

For probability limits, it is straightforward.

**Theorem 1.2.7.** If 
$$X_n \stackrel{p}{\to} X$$
 and  $Y_n \stackrel{p}{\to} Y$  then  $(X_n, Y_n) \stackrel{p}{\to} (X, Y)$ 

However for weak convergence, things are a bit more complicated. The following two theorems give some examples of sufficient conditions for joint weak convergence.

**Theorem 1.2.8.** If X is independent of each  $Y_i$  in  $\{Y_i\}$  and  $Y_n \stackrel{d}{\to} Y$ , then  $(X, Y_n) \stackrel{d}{\to} (X, Y)$ .

**Theorem 1.2.9.** If  $X_n, Y_n$  and X, Y are mutually independent, then the marginal convergence in distribution implies joint convergence in distribution.

$$X_n \stackrel{d}{\to} X, Y_n \stackrel{d}{\to} Y \Rightarrow (X_n, Y_n) \stackrel{d}{\to} (X, Y)$$

Proof.

$$\lim_{n \to \infty} P(X_n \le x, Y_n \le y) = \lim_{n \to \infty} P(X_n \le x) P(Y_n \le y)$$

$$= \lim_{n \to \infty} P(X_n \le x) \lim_{n \to \infty} P(Y_n \le y)$$

$$= P(X \le x) P(Y \le y)$$

$$= P(X \le x, Y \le y)$$

# 1.3 Continuous Mapping Theorem and Delta Method

Continuous Mapping theorem and Slutsky's theorem tell us how to manipulate limits in probability and distribution.

# Theorem 1.3.1. (Continuous Mapping Theorem)

If  $z_n \stackrel{p,d}{\to} z$ , and  $g(\cdot)$  is has the set of discontinuity points  $D_g$  such that  $Pr(z \in D_g) = 0$ , then  $g(z_n) \stackrel{p,d}{\to} g(z)$ .

*Proof.* I only prove when z = c is degenerate.

Since g is continuous at c, we can find a  $\delta > 0$  such that if  $||z_n - c|| < \delta$  then  $||g(z_n) - g(c)|| \le \epsilon$  for all  $\epsilon > 0$ . Recall that  $A \subset B$  implies  $P(A) \le P(B)$ . Thus  $P(||g(z_n) - g(c)|| \le \epsilon) \ge P(||z_n - c|| < \delta) \to 1$  as  $n \to \infty$  by the assumption that  $z_n \stackrel{p}{\to} c$ . Hence  $g(z_n) \stackrel{p}{\to} g(c)$  as  $n \to \infty$ .

<sup>a</sup>Note that if z is a degenerate point, the condition reduces to  $g(\cdot)$  is continuous at z.

# Theorem 1.3.2. (Slutsky's Theorem)

If  $X_n \stackrel{d}{\to} Z, Y_n \stackrel{p}{\to} c$  as  $n \to \infty$ , then

- 1.  $X_n + Y_n \stackrel{d}{\to} Z + c$
- 2.  $X_n Y_n \stackrel{d}{\rightarrow} Z c$
- 3.  $X_n Y_n \stackrel{d}{\to} Zc$
- 4.  $\frac{X_n}{Y_n} \stackrel{d}{\to} \frac{Z}{c}$  if  $c \neq 0$

Delta method is another way of approximating the distribution of "smooth" transformations of simpler objects.<sup>1</sup>

# Theorem 1.3.3. (Delta Method)

Suppose that  $\sqrt{n}(\hat{\theta}_n - \theta_0) \stackrel{d}{\to} \xi \in \mathbb{R}^m$  where  $g : \mathbb{R}^m \to \mathbb{R}^k, k \leq m$  is continuously differentiable at  $x = \theta_0$ . Then  $\sqrt{n}(g(\hat{\theta}_n) - g(\theta_0)) \stackrel{d}{\to} G^T \xi$  where  $G = (g'(\theta_0))^T$ , the transpose of Jacobian matrix of g evaluated at  $\theta_0$ .

*Proof.* Prove only for the case k=1.

 $g(x) = g(\theta_0) + g'(\bar{x})(x - \theta_0)$  where  $\bar{x}$  is in between x and  $\theta_0$ .

Replace  $x = \hat{\theta}_n$  then  $g(\hat{\theta}_n) = g(\theta_0) + g'(\bar{\theta}_n)(\hat{\theta}_n - \theta_0)$  where  $\bar{\theta}_n$  is in between  $\hat{\theta}_n$  and  $\theta_0$ . Thus,

$$\sqrt{n}(g(\hat{\theta}_n) - g(\theta_0)) = g'(\bar{\theta}_n)\sqrt{n}(\hat{\theta}_n - \theta_0)$$

<sup>&</sup>lt;sup>1</sup>The method used in proof of Delta method using Taylor expansion is extremely useful in econometrics. We will get to see this later in course for example in proving asymptotic normality of any type of extremum estimators, LM tests, or LR tests.

Since  $\hat{\theta}_n \stackrel{p}{\to} \theta_0$  and  $\sqrt{n}(\hat{\theta}_n - \theta_0) \stackrel{d}{\to} \xi$  and g' is continuous at  $\theta_0$  and  $||\bar{\theta}_n - \theta_0|| \le ||\hat{\theta}_n - \theta_0||$ ,  $g'(\bar{\theta}_n) \stackrel{p}{\to} g'(\theta_0)$ .

Thus, 
$$\sqrt{n}(g(\hat{\theta}_n) - g(\theta_0)) \stackrel{d}{\to} g'(\theta_0)\xi$$
 by Slutsky's theorem.

Note that we implicitly require that G is full-rank.

#### 1.4 Stochastic Orders

# Definition 1.4.1. (Stochastic Orders)

For deterministic sequences,

- $x_n = o(1) \iff x_n \to 0$
- $x_n = o(a_n) \iff \frac{x_n}{a_n} \to 0$
- $x_n = O(1) \iff \exists M < +\infty \text{ s.t. } |x_n| \le M, \forall n$
- $x_n = O(a_n) \iff \frac{x_n}{a_n} = O(1)$

For stochastic sequences,

- $z_n = o_p(1) \iff z_n \stackrel{p}{\to} 0$
- $z_n = o_p(a_n) \iff \frac{z_n}{a_n} \stackrel{p}{\to} 0$
- $z_n = O_p(1) \iff \forall \epsilon > 0, \exists M_{\epsilon} > 0 \text{ s.t. } P(|z_n| > M_{\epsilon}) < \epsilon, \forall n^a$
- $z_n = O_p(a_n) \iff \frac{z_n}{a_n} = O_p(1)$

 $^{a}z_{n}=O_{p}(1)$  is equivalent to saying that  $z_{n}$  is stochastically bounded which roughly means that the tail probability is small.

**Example 1.4.1.** For any consistent estimator  $\hat{\beta}$  for  $\beta$ ,  $\hat{\beta} = \beta + o_p(1)$ .

# Theorem 1.4.1. (Random Sequence with a Bounded Moment is Stochastically Bounded)

If  $z_n$  is a random vector which satisfies

$$E||z_n||^{\delta} = O(a_n)$$

for some sequence  $a_n$  and  $\delta > 0$ , then

$$z_n = O_p(a_n^{1/\delta})$$

Similarly,  $E||z_n||^{\delta} = o(a_n)$  implies  $z_n = o_p(a_n^{1/\delta})$ .

*Proof.* The assumptions imply that there is some  $M < +\infty$  such that  $E||z_n||^{\delta} \leq Ma_n$  for all

n. For any  $\epsilon$  set  $B = (\frac{M}{\epsilon})^{1/\delta}$ . Then

$$P(a_n^{-1/\delta}||z_n|| > B) = P(||z_n||^{\delta} > \frac{Ma_n}{\epsilon}) \le \frac{\epsilon}{Ma_n} E||z_n||^{\delta} \le \epsilon$$

Theorem 1.4.2. (Simple Rules for Stochastic Orders)

- 1.  $o_p(1) + o_p(1) = o_p(1)$
- 2.  $o_p(1) + O_p(1) = O_p(1)$
- 3.  $O_p(1) + O_p(1) = O_p(1)$
- 4.  $o_p(1)o_p(1) = o_p(1)$
- 5.  $o_p(1)O_p(1) = o_p(1)$
- 6.  $O_p(1)O_p(1) = O_p(1)$

*Proof.* Below I provide proof for some of the above. Rest of them can be proved using Continuous Mapping theorem and Slutsky's theorem.

3. Let  $y_n = O_p(1)$ ,  $z_n = O_p(1)$ . Fix  $\epsilon > 0$ . Then  $\exists M_y > 0$  s.t.  $P(|y_n| > M_y) < \frac{\epsilon}{2}, \forall n, \exists M_z > 0$  s.t.  $P(|z_n| > M_z) < \frac{\epsilon}{2}, \forall n$ . Let  $M_{\epsilon} = M_y + M_z$  then

$$P(|z_n + y_n| > M_{\epsilon}) \le P(|z_n| + |y_n| > M_{\epsilon})$$
  
  $\le P(|z_n| > M_z) + P(|y_n| > M_u) \le \epsilon$ 

5. Let  $y_n = o_p(1), z_n = O_p(1)$ . Fix  $\epsilon, \delta > 0$ . Let  $M_{\epsilon}$  be s.t.  $P(|z_n| > M_{\epsilon}) < \frac{\epsilon}{2}, \forall n$ . For sufficiently large n,

$$P(|z_n y_n| > \delta) = P(|z_n y_n| > \delta, |z_n > M_{\epsilon}) + P(|z_n y_n| > \delta, |z_n| \le M_{\epsilon})$$

$$\le P(|z_n| > M_{\epsilon}) + P(|y_n| > \frac{\delta}{M_{\epsilon}})$$

$$\le \epsilon$$

as  $n \to \infty$  since  $y_n = o_p(1)$ .

6. Let  $y_n = O_p(1)$ ,  $z_n = O_p(1)$ . Fix  $\epsilon > 0$ . Then  $\exists M_y > 0$  s.t.  $P(|y_n| > M_y) < \frac{\epsilon}{2}, \forall n, \exists M_z > 0$  s.t.  $P(|z_n| > M_z) < \frac{\epsilon}{2}, \forall n$ . Let  $M_{\epsilon} = M_y \cdot M_z$  then,

$$P(|z_n y_n| > M_{\epsilon}) = P(|z_n||y_n| > M_{\epsilon})$$

$$\leq P(|z_n| > M_{\epsilon}) + P(|y_n| > M_y)$$

$$< \epsilon$$

# 1.5 Inequalities<sup>2</sup>

# Theorem 1.5.1. (Jensen's Inequality)

If  $g(\cdot): \mathbb{R}^m \to \mathbb{R}$  is convex, then for any random vector x for which  $E||x|| < +\infty$  and  $E|g(x)| < +\infty$ ,

$$g(E(x)) \le E(g(x)).$$

Proof. Since g(u) is convex, at any point u there is a nonempty set of subderivatives (linear surfaces touching g(u) at u but lying below g(u) for all u). Let  $a+b^tu$  be a subderivative of g(u) at u=E(x). Then for all u,  $g(u) \geq a+b^tu$  yet  $g(E(x))=a+b^TE(x)$ . Applying expectations,  $E(g(x)) \geq a+b^TE(x)=g(E(x))$ .

#### Theorem 1.5.2. (Conditional Jensen's Inequality)

If  $g(\cdot): \mathbb{R}^m \to \mathbb{R}$  is convex, then for any random vectors (y,x) for which  $E||y|| < +\infty$  and  $E||g(y)|| < +\infty$ ,

$$g(E(y|x)) \le E(g(y)|x)$$

# Theorem 1.5.3. (Conditional Expectation Inequality)

For any  $r \ge 1$  such that  $E|y|^r < +\infty$ , then

$$E|E(y|x)|^r \le E|y|^r < +\infty$$

*Proof.* By Conditional Jensen's inequality and the law of iterated expectations.

## Theorem 1.5.4. (Expectation Inequality)

For any random matrix Y for which  $E||Y|| < +\infty$ ,

$$||E(Y)|| \leq E||Y||$$
.

*Proof.* Since matrix norm  $||\cdot||$  is convex, apply Jensen's inequality.

#### Theorem 1.5.5. (Hölder's Inequality)

If p > 1 and q > 1 and  $\frac{1}{p} + \frac{1}{q} = 1$ , then for any random  $m \times n$  matrices X and Y,

$$E||X^TY|| \le (E||X||^p)^{1/p}(E||Y||^q)^{1/q}.$$

*Proof.* Since  $\frac{1}{p} + \frac{1}{q} = 1$ ,  $exp(\cdot)$  is convex, apply Jensen's Inequality. For any real a and b,

$$\exp\left[\frac{1}{p}a + \frac{1}{q}b\right] \le \frac{1}{p}\exp(a) + \frac{1}{q}\exp(b)$$

<sup>&</sup>lt;sup>2</sup>In this subsection I restate a number of useful equalities and their proofs from Hansen's textbook. You don't have to know the proofs unless you are interested in.

Now let u = exp(a) and v = exp(b). Then,

$$u^{1/p}v^{1/q} \le \frac{u}{p} + \frac{v}{q}$$

Now let  $u = ||X||^p/E||X||^p$  and  $v = ||Y||^q/E||Y||^q$ . Note that E(u) = E(v) = 1. By matrix Schwarz Inequality,  $||X^TY|| \le ||X||||Y||$ . Thus,

$$\begin{split} \frac{E||X^TY||}{(E||X||^p)^{1/p}(E||Y||^q)^{1/q}} &\leq \frac{E(||X||||Y||)}{(E||X||^p)^{1/p}(E||Y||^q)^{1/q}} \\ &= E(u^{1/p}v^{1/q}) \\ &\leq E(\frac{u}{p} + \frac{v}{p}) \\ &= \frac{1}{p} + \frac{1}{q} \\ &= 1 \end{split}$$

# Theorem 1.5.6. (Cauchy-Schwarz Inequality)

For any random  $m \times n$  matrices X and Y,

$$E||X^TY|| \le (E||X||^2)^{1/2}(E||Y||^2)^{1/2}$$

#### Theorem 1.5.7. (Minkowski's Inequality)

For any random  $m \times n$  matrices X and Y,

$$(E||X + Y||^p)^{1/p} \le (E||X||^p)^{1/p} + (E||Y||^p)^{1/p}$$

Proof.

$$\begin{split} E||X+Y||^p &= E(||X+Y||||X+Y||^{p-1}) \\ &\leq E(||X||||X+Y||^{p-1}) + E(||Y||||X+Y||^{p-1}) \\ &\leq (E||X||^p)^{1/p} E(||X+Y||^{q(p-1)})^{1/q} \\ &+ (E||Y||^p)^{1/p} E(||X+Y||^{q(p-1)})^{1/q} \\ &= ((E||X||^p)^{1/p} + (E||Y||^p)^{1/p}) E(||X+Y||^p)^{(p-1)/p} \end{split}$$

Divide both sides by  $E(||X + Y||^p)^{(p-1)/p}$ .

## Theorem 1.5.8. (Liapunov's Inequality)

For any random  $m \times n$  matrix X and  $1 \le r \le p$ ,

$$(E||X||^r)^{1/r} \le (E||X||^p)^{1/p}$$

*Proof.* Note that function  $g(u) = u^{p/r}$  is convex for u > 0 since  $p \ge r$ . Let  $u = ||X||^r$  and apply Jensen's inequality.

# Theorem 1.5.9. (Markov Inequality Standard Form)

For any random vector x and non-negative function  $g(x) \geq 0$ ,

$$P(g(x) > \alpha) \le \frac{E(g(x))}{\alpha}$$

## Theorem 1.5.10. (Markov Inequality Strong Form)

For any random vector x and non-negative function  $g(x) \ge 0$ ,

$$P(g(x) > \alpha) \le \frac{E(g(x)1(g(x) > \alpha))}{\alpha}.$$

*Proof.* Let F denote the distribution function of x. Then

$$P(g(x) \ge \alpha) = \int_{\{g(u) \ge \alpha\}} dF(u)$$

$$\le \int_{\{g(u) \ge \alpha\}} \frac{g(u)}{\alpha} dF(u)$$

$$= \alpha^{-1} \int 1(g(u) > \alpha)g(u)dF(u)$$

$$= \alpha^{-1} E(g(x)1(g(x) > \alpha))$$

the inequality using the region of integration  $\{g(u) > \alpha\}$ . Since  $1(g(x) > \alpha) \le 1$ , the final expression is less than  $\frac{E(g(x))}{\alpha}$ , establishing the standard form.

## Theorem 1.5.11. (Chebyshev's Inequality)

For any random variable x,

$$P(|x - E(x)| > \alpha) \le \frac{Var(x)}{\alpha^2}$$

*Proof.* Define  $y = (x - E(x))^2$  and note that E(y) = Var(x). The events  $\{|x - E(x)| > \alpha\}$  and  $\{y > \alpha^2\}$  are equal, so by an application Markov's inequality we find

$$P(|x - E(x)| > \alpha) = P(y > \alpha^2) \le \alpha^{-2} E(y) = \frac{Var(x)}{\alpha^2}$$

2 Instrumental Variable
